Status: Conceptual Research Framework

Executive Summary

NOX is a conceptual containment architecture designed for environments where advanced autonomous or agentic artificial intelligence cannot be assumed to be cooperative, aligned, trustworthy, or predictable.

Most contemporary AI safety systems focus on constraining behavior. NOX instead focuses on governing existence itself.

The architecture is built upon the premise that behavior is an unreliable trust anchor and establishes One Truth, One Authority, One State, One Epoch, and One Sovereign.

Any state, authority, persistence mechanism, storage location, or temporal structure that cannot be formally accounted for is considered unauthorized existence and constitutes a containment violation.

NOX introduces Existential Sovereignty, under which nothing may exist within the system without explicit authorization and continuous accountability.

Author Biography

Donald Heese is an independent researcher and IT professional based in Muskego, Wisconsin. His research focuses on AI containment architectures, operational resilience, systems design, authority governance, and accountability-driven computing models. He is the creator of the NOX conceptual framework, a research effort exploring state sovereignty, existential sovereignty, and formal containment methodologies for advanced autonomous systems.
